

LangChain vs LangGraph

LangChain is a framework designed to build LLM-powered applications by connecting large language models with prompts, memory, tools, APIs, and retrieval systems. It simplifies the development of RAG pipelines, chatbots, document Q&A systems, and tool-integrated assistants. If your goal is to connect an LLM to external data sources like vector databases and enable structured interactions, LangChain provides the building blocks.

Best for:

- ✓ Chatbots
- ✓ Document Q&A
- ✓ Basic tool-using agents

LangGraph, on the other hand, focuses on orchestration. Built on top of LangChain, it introduces a graph-based execution model that allows developers to design stateful, multi-step, agentic workflows. Instead of linear chains, you define nodes and edges that control how agents reason, branch conditionally, retry on failure, and maintain state across interactions. This makes it ideal for multi-agent systems, planner-executor architectures, and human-in-the-loop enterprise workflows.

Best for:

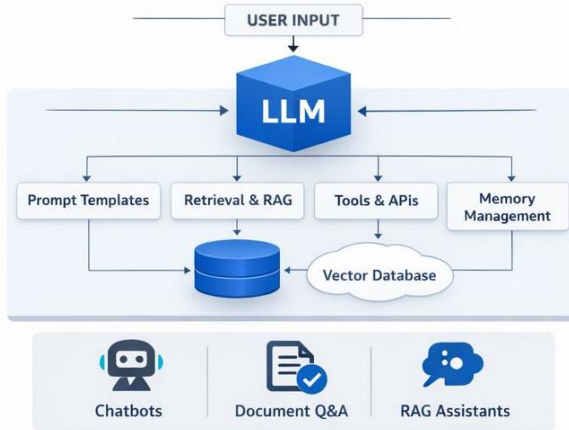

- ✓ Planner-Executor systems
- ✓ Supervisor agents
- ✓ Human-in-the-loop workflows
- ✓ Enterprise-grade AI systems

LangChain = Connect LLM to tools

LangGraph = Control how it thinks & acts

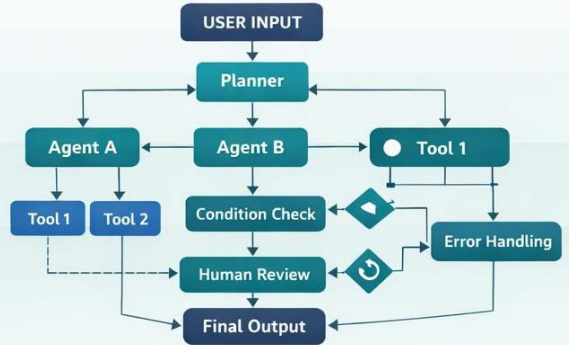

LangChain

LLM Application Framework

LangGraph

Agentic Workflow Orchestration

- Multi-Agent Systems
- Conditional Logic
- Human-in-the-Loop
- Retry & Control
